1. Introduction

Droughts and **overgrazing** can result in rangeland **degradation**. This is particularly true for the **semi-arid rangelands** of Namibia. To mitigate rangeland degradation beyond a point of no return it is important to identify **early warning signs**. As vegetation responds to degradation processes, **taxonomic** and **functional diversity** could be valuable indicators for rangelands approaching a tipping point.

Degraded Namibian rangeland

Research questions:

1. How does grazing pressure affect functional trait space?
2. Does management affect taxonomic and functional diversity?
3. Is functional diversity a suitable early-warning indicator of rangeland degradation?

3. Results

Taxonomic species richness does not differ significantly along the grazing gradient ($p=0.278$)

None of the 9 functional alpha diversity indices were affected by grazing pressure. See functional richness against grazing pressure as an example ($p=0.139$)

Functional richness in a four-dimensional space based on Principal Component Analysis

Communal farms: 0.989
Freehold farms: 0.646

The plant communities on communal rangeland filled more of the total trait space

Presence of *Eragrostis rigidior* along the grazing gradient

Eragrostis rigidior: important palatable grass species

Presence of *Sida cordifolia* along the grazing gradient

Sida cordifolia: exotic; invader of overgrazed fields

Eragrostis rigidior occurred mainly on freehold farms and at larger distances from water points, while the invader *Sida cordifolia* occurred mostly on communal lands and closer to water points → possible indicator species of rangeland degradation?

2. Study Design & Methods

- Leaf area
- Leaf dry matter content
- Specific leaf area
- C & N content
- Plant height
- Plant type

Study setup

- 2 management types: communal rangelands with year-round grazing, and freehold farms with rotational grazing
- 8 farms, each with 2 grazing gradients
- 9 observational plots along a gradient from highest grazing pressure (close to water point)

Taxonomic data collection

- In each plot: 2 quadrats in open grassland, 2 in subcanopy areas
- In each quadrat: herbaceous plant inventory including species-specific cover estimation

Functional trait collection

- Sampling of all dominant species
- Processing of leaf traits (e.g., leaf area and leaf dry matter content)
- Setting up a functional trait database that can be related to species inventories

4. Conclusions

- Trait space — based on leaf traits, plant height, and plant type — was unrelated to the grazing pressure gradient
- Taxonomic and functional diversity were unrelated to the grazing pressure gradient, irrespective of the two management systems
- In contrast to our expectation, we found slightly higher functional diversity in the more degraded, communal farms
- Functional diversity is not a suitable early-warning indicator to detect early-stage rangeland degradation
- Certain species show potential as indicator species of rangeland degradation

5. Outlook

- Complement functional trait database with C/N data, and re-evaluate functional diversity analysis; include functional beta diversity indices
- Since distance from water point is merely a proxy of grazing pressure, develop a more accurate grazing index
- Conduct multivariate analyses on functional diversity indices to determine importance of environmental variables
- Further evaluation of potential indicator species

Initial Principal Component Analysis to develop a grazing index
